Instructions for ATD-8615 Wheel Balancer

Make restain the bubble is in the middle of the black cricle before using the halancer. This
is necessary to guarantee accreacy of balance. See Arrow 1, Figure A.

The hubble (circular level) in the ATB balancer is mounted into the fap of the head assembly cone by three adjustable sciews, if the bubble is not in the middle of the black circle when the head assembly is resting on the support shall and not in use, adjustment can easily be made by sciewing up or down on the screws which hold the bubble in the balancer. Turn one of the screws downward the bubble will move away from you, furn the screw upward the bubble will move toward you. Adjustment of the bubble must be made with the head assembly sitting on the support shalt.

 Always keep No. 10 weight oit around the pivot pin located in the upper end of the balancer support shalt. This will guarantee a minimum of friction and altow your balancer to operate accurately. See Arrow 2, Figure A.

Make sure that the FOUR steel guide rods located in the head assembly are free of dirt and well oiled to insure easy and accurate seating of the wheel on the balancer and to eliminate rust. See Arrow 3, Figure A.

Be sure that the support shalt is firmly secured in the stand by lightening the nul as indicated in Airow 4, Figure A. This is necessary for the proper function of the balancer.

 Remove the fire and wheel from call and scrape extra mud from the inderside of the while.
 Check the high hole in the wheel, it may need minor scraping to insure uniform seating on the batancer cene.

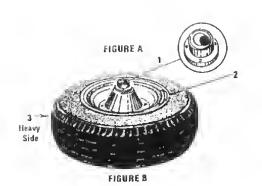

Place the line and wheel on the balancer using light downward pressure to guarantee accurate sealing. Let balancer settle to a stop.

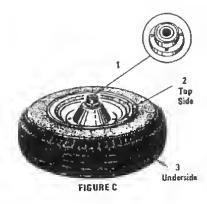

11 there is an out-of-balance condition the heavy side of the fire and wheel will cause the bubble to move outside the black circle in the opposite direction to the heavy side, See Arrow 1. Figure B.

Lay a weight on the fight side of the rim closest to the bubble. See Arrow 2, Figure B. If the list weight does not bring the bubble back to the middle of the black circle, then remove the weight and lay a larger or smaller weight in place to bring the bubble to the middle, as shown in Figure C. Arrow t.

4. Remove the tire and wheel from the balancer and place the proper amount of weight needed equally on both sides of the wheel. For example, if it requires a total of 3 ounces to properly balance the wheel, attach a 1-1/2 ounce weight on the top of the wheel rim and a 1-1/2 ounce weight on the underside of the wheel rim. Divide the weights when 1 ounce or more is to be used.

If you need to use weight which cannot be divided equally, attach the heaviest weight on the underside of the wheel rim and the lighter weight on the top of the wheel rim. For instance, if you need a lotal of 2-1/2 ounces, attach 1-1/2 ounces on the underside and 1 ounce on the top side, making a total of 2-1/2 ounces.

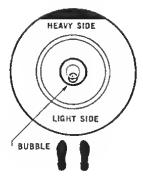

5. In case the pivot pin in the balancer support shall becomes worn, remove it with long-nosed pliers and put in a new one. Use a small amount of Permatex No. 1 on the end of the pin which is to be inserted into the shalt. Permatex with harden and secure the pin firmly. It you need parts see your local ATD Jobber.

See reverse side for using the 4 weight system or ABC system.

Illustration of wheel and tile assembly out of balance and your standing position during use
of the balancer.

Be sure that the support shaft is firmly secured in the stand by hightening the nul. This is necessary for the correct function of the balancer. Make sure the bubble is in the middle of the black dicte before using the balancer. This is to guarantee accuracy of balance.

The bubble (circular level) is mounted into the lop of the head assembly cone by three adjustable screws. If the bubble is not exactly in the middle of the black circle when the head assembly is resting on the support shalt and not being used, adjustment can be made by lutning up or down on the screws which hold the bubble in the balancer. If you turn one of the screws downward the bubble will move away from you, turn the screw upward the bubble will move toward you. Adjustment of the bubble must be made with the head assembly silling on the support shall.

After you have determined which four weights to use and have them placed in pairs, as shown in Fig. 3, move the pairs in opposite directions from each other around the rim equal distance from the starting point until the bubble is centered in the black circle.

4. Draw a vertical chalk line on the fread directly in the middle of each pair of weights. To accurately locate lines, sight through the middle of the weights to the middle of the balancer. Remove the two pairs of weights and till the wheel from the balancer. Attach one weight on the inside of rim directly in line with each chalk mark on the line.
